Technical University Delft

Outline

- 1** The delay monad
- 2** Stream processors
- 3** Formal languages

Lecture plan

- 1 The delay monad
- 2 Stream processors
- 3 Formal languages

The delay monad

The **delay monad** embeds potentially non-terminating computations in Agda:

mutual

 data Delay (A : Set) : Set where

 now : A → Delay A

 later : Delay' A → Delay A

 record Delay' (A : Set) : Set where

 coinductive

 field force : Delay A

 open Delay' public

Delayed values

Classically, any $x : \text{Delay } A$ is either `never` or `laters k a` for some $k : \mathbb{N}$ and $a : A$:

`never : Delay A`

`never = later (λ where .force → never)`

`laters : N → A → Delay A`

`laters zero a = now a`

`laters (suc n) a = later`

`(λ where .force → laters n a)`

Exercise. Implement

`iter : (A → A ⊕ B) → A → Delay B.`

Implementing bind for the delay monad

$_ \gg= _ : \text{Delay } A \rightarrow (A \rightarrow \text{Delay } B) \rightarrow \text{Delay } B$

$\text{now } x \gg= f = f x$

$\text{later } d \gg= f = \text{later } \lambda \text{ where}$

$.force \rightarrow d .force \gg= f$

Convergence of delayed values

```
data _ $\Downarrow$ _ {A} : Delay A → A → Set where
```

```
  now : (x : A) → now x  $\Downarrow$  x
```

```
  later : d .force  $\Downarrow$  x → later d  $\Downarrow$  x
```

```
 $\Downarrow$ -unique : d  $\Downarrow$  x → d  $\Downarrow$  y → x ≡ y
```

```
 $\Downarrow$ -unique (now x) (now y) = refl
```

```
 $\Downarrow$ -unique (later p) (later q) =  $\Downarrow$ -unique p q
```

Bisimulation of delayed values

mutual

```
data _~_ {A} : Delay A → Delay A → Set where
  now : (x : A) → now x ~ now x
  later : x ~' y → later x ~ later y
```

record _~'_ (x y : Delay' A) : Set where

coinductive

field

```
  force : x.force ~ y.force
```

open _~'_ public

Monad laws for Delay

`refl~ : (x : Delay A) → x ~ x`

`refl~ (now x) = now x`

`refl~ (later x) = later λ where`

`.force → refl~ (x .force)`

`now-»= : (x : A) (f : A → Delay B)`

`→ now x »= f ~ fx`

`now-»= xf = refl~ (fx)`

Exercise. State and prove the second and third monad laws `»=-now` and `»=-assoc`.

Weak bisimilarity

Since we don't really care about the number of laters, we can make more things bisimilar:

mutual

```
data _~D_ {A} : Delay A → Delay A → Set where
```

```
  value :  $d_1 \Downarrow x \rightarrow d_2 \Downarrow x \rightarrow d_1 \sim_D d_2$ 
```

```
  later :  $d_1 \sim_{D'} d_2 \rightarrow \text{later } d_1 \sim_D \text{later } d_2$ 
```

```
record _~D'_ (x y : Delay' A) : Set where
```

coinductive

```
  field force : x.force ~D y.force
```

```
open _~D'_ public
```

The partiality monad

Instead of making more elements bisimilar, we can quotient the **Delay** monad by $x \text{ later } x$.

This leads to the definition of the **partiality monad** by Altenkirch, Danielsson & Kraus (FoSSaCS 2017) as a *quotient inductive-inductive type* (QIIT).

Outline

- 1** The delay monad
- 2** Stream processors
- 3** Formal languages

Stream processors

A **stream processor** describes how to transform a stream of *As* into a stream of *Bs*:

mutual

 data **SP** (*A B* : Set) : Set where

get : (*A* → SP *A B*) → SP *A B*

put : *B* → SP' *A B* → SP *A B*

 record **SP'** (*A B* : Set) : Set where

 coinductive

 field **force** : SP *A B*

 open SP'

There can only be a finite number of **gets** before there must be a **put**.

Example stream processor: summing elements pairwise

sum2by2 : SP N N

sum2by2 =

get $\lambda x \rightarrow$

get $\lambda y \rightarrow$

put $(x + y)$

λ where .force \rightarrow sum2by2

Running a stream processor

`run : SP A B → Stream A → Stream B`

`run (get f) xs = run (f(xs .headS)) (xs .tailS)`

`run (put y sp) xs .headS = y`

`run (put y sp) xs .tailS = run (sp .force) xs`

`sum2by2-nats :`

`takeS 5 (run sum2by2 nats)`

`≡ (1 :: 5 :: 9 :: 13 :: 17 :: [])`

`sum2by2-nats = refl`

A slightly more interesting example

Question. What does the stream processor below do?

mutual

 sums : SP N N

 sums = get $\lambda n \rightarrow$ sumN n o

 sumN : N → N → SP N N

 sumN zero a = put a where .force → sums

 sumN (suc n) a = get $\lambda k \rightarrow$ sumN n (a + k)

Let's run it on nats!

Composing stream processors

If we have a $\text{SP } A \ B$ and a $\text{SP } B \ C$, we can apply them in sequence to a $\text{Stream } A$ to get a $\text{Stream } C$.

Exercise. Do the same with a single processor:

$\text{compose} : \text{SP } A \ B \rightarrow \text{SP } B \ C \rightarrow \text{SP } A \ C$

$\text{compose-correct} :$

$$(p_1 : \text{SP } A \ B) (p_2 : \text{SP } B \ C) (s : \text{Stream } A) \rightarrow \\ \text{run} (\text{compose } p_1 p_2) s \sim \text{run } p_2 (\text{run } p_1 s)$$

Outline

- 1 The delay monad
- 2 Stream processors
- 3 Formal languages

Formal languages, coinductively

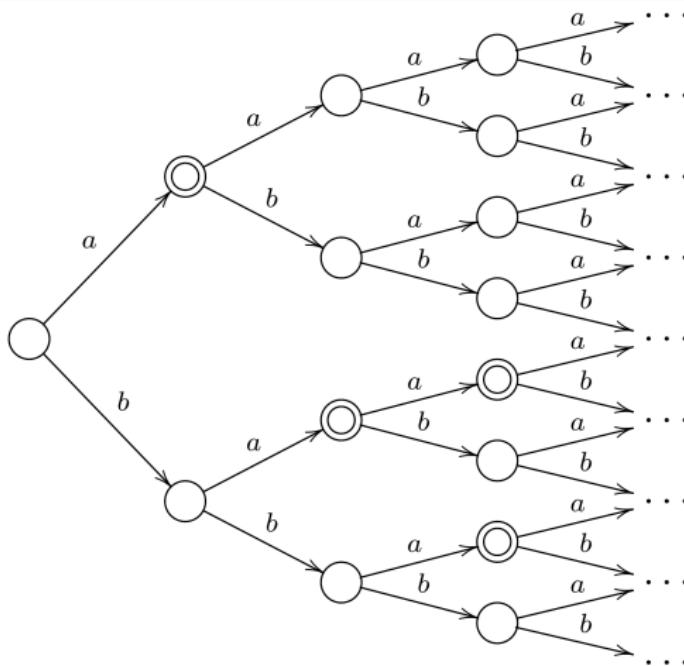

We can describe a formal language l (= a set of strings) over an alphabet A with two pieces of data:

- whether it is **nullable**
(= contains the empty string)
- for each $a \in A$, the **derivative**
 $\delta_a(l) = \{s \mid a \cdot s \in l\}.$

Note that this is a *coinductive* description of formal languages.

Formal languages as (infinite) tries

We can visualize a language as an infinite **trie**:

Coinductive formal languages in Agda

```
module FormalLanguages
  (A : Set) (_ $\stackrel{?}{=}$ _ : DecidableEquality A) where

  record Lang : Set where
    coinductive
    field
       $\nu$  : Bool
       $\delta$  : A  $\rightarrow$  Lang
  open Lang public
```

Some simple languages

$\emptyset : \text{Lang}$

$\emptyset . v = \text{false}$

$\emptyset . \delta = \lambda _ \rightarrow \emptyset$

$\varepsilon : \text{Lang}$

$\varepsilon . v = \text{true}$

$\varepsilon . \delta = \lambda _ \rightarrow \emptyset$

$\text{char} : A \rightarrow \text{Lang}$

$\text{char } a . v = \text{false}$

$\text{char } a . \delta b = \text{if does } (a \stackrel{?}{=} b) \text{ then } \varepsilon \text{ else } \emptyset$

Language membership and tabulation

$_ \ni _ : \text{Lang} \rightarrow \text{List } A \rightarrow \text{Bool}$

$l \ni [] = l . \nu$

$l \ni (x :: xs) = l . \delta x \ni xs$

$\text{trie} : (\text{List } A \rightarrow \text{Bool}) \rightarrow \text{Lang}$

$\text{trie } f . \nu = f []$

$\text{trie } f . \delta a = \text{trie } (f \circ (a :: _))$

Operations on languages

complement : Lang \rightarrow Lang

complement $l . \nu = \text{not } (l . \nu)$

complement $l . \delta x = \text{complement} (l . \delta x)$

\cup : Lang \rightarrow Lang \rightarrow Lang

$(l_1 \cup l_2) . \nu = l_1 . \nu \vee l_2 . \nu$

$(l_1 \cup l_2) . \delta x = l_1 . \delta x \cup l_2 . \delta x$

\cap : Lang \rightarrow Lang \rightarrow Lang

$(l_1 \cap l_2) . \nu = l_1 . \nu \wedge l_2 . \nu$

$(l_1 \cap l_2) . \delta x = l_1 . \delta x \cap l_2 . \delta x$

Language concatenation

We run into a problem when defining concatenation of languages:

$_ \cdot _ : \text{Lang} \rightarrow \text{Lang} \rightarrow \text{Lang}$

$(l_1 \cdot l_2) . \nu = l_1 . \nu \wedge l_2 . \nu$

$(l_1 \cdot l_2) . \delta x = (\text{if } l_1 . \nu \text{ then } l_2 \text{ else } \emptyset) \cup (l_1 . \delta x \cdot l_2)$

Error: Termination checking failed for $_ \cdot _$.

Problematic calls: $l_1 . \delta x \cdot l_2$

The guardedness is obscured by the call to \cup .

Sized types to the rescue

```
record Lang (i : Size) : Set where
  coinductive
  field
    ν : Bool
    δ : {j : Size < i} → A → Lang j
  open Lang public
```

Language concatenation with sizes

We can define union to be size-preserving:

$$\underline{\cup} : \text{Lang } i \rightarrow \text{Lang } i \rightarrow \text{Lang } i$$

$$(l_1 \cup l_2) . \nu = l_1 . \nu \vee l_2 . \nu$$

$$(l_1 \cup l_2) . \delta x = l_1 . \delta x \cup l_2 . \delta x$$

This allows the definition of concatenation to pass:

$$\underline{\cdot} : \text{Lang } i \rightarrow \text{Lang } i \rightarrow \text{Lang } i$$

$$(l_1 \cdot l_2) . \nu = l_1 . \nu \wedge l_2 . \nu$$

$$(l_1 \cdot l_2) . \delta x = (\text{if } l_1 . \nu \text{ then } l_2 \text{ else } \emptyset) \cup (l_1 . \delta x \cdot l_2)$$

Definition of Kleene star

$\underline{_}^*$: Lang $i \rightarrow \text{Lang } i$

$(l^*) . \nu = \text{true}$

$(l^*) . \delta x = l . \delta x \cdot (l^*)$

Arden's rule

Arden's rule states: for a non-nullable language k , if $l = (k \cdot l) \cup m$, then $l = (k^*) \cdot m$

Question. How do we state this rule in Agda?

¹or path equality in cubical Agda.

Arden's rule

Arden's rule states: for a non-nullable language k , if $l = (k \cdot l) \cup m$, then $l = (k^*) \cdot m$

Question. How do we state this rule in Agda?

Answer. Using bisimulation!¹

¹or path equality in cubical Agda.

Bisimulation of languages

```
record _~⟨_⟩~_
  (l1 : Lang ∞) (i : Size) (l2 : Lang ∞) : Set where
    coinductive
      field
        ν : l1.ν ≡ l2.ν
        δ : {j : Size < i} (x : A) → l1.δ x ~⟨ j ⟩~ l2.δ x
  open _~⟨_⟩~_
```

Arden's rule in Agda

Now we can state Arden's rule:

$$\text{arden} : (k \ l \ m : \text{Lang } \infty) \rightarrow \\ l \sim \langle \infty \rangle \sim (k \cdot l) \cup m \rightarrow l \sim \langle \infty \rangle \sim (k^*) \cdot m$$

For the full proof, see *Equational Reasoning about Formal Languages in Coalgebraic Style* by Andreas Abel (2016).
